Problem 1 (10 pts)

For this problem, we explore the issue of truthfulness in the Gale-Shapley algorithm for Stable Matching. Show that a participant can improve its outcome by lying about its preferences. Consider $r \in R$. Suppose r prefers p to p', but p and p' are low on r's preference list. Show that it is possible that by switching the order of p and p' on r's preference list, r achieves a better outcome, e.g., is matched with a p'' higher on the preference list than the one if the actual order was used.

Hint: Prove the claim by finding one specific instance of stable matching problem and comparing the stable matching before and after the switching.

Solution

Setup. Let the two sides be:

```
Residents (receivers): R = \{r, s, t\}, Programs (proposers): P = \{p, p', q\}.
```

We run the program-proposing Gale-Shapley algorithm.

True Preferences

• Resident $r: q \succ p \succ p'$

• Resident $s: p \succ q \succ p'$

• Resident $t: p \succ p' \succ q$

• Program $p: r \succ s \succ t$

• Program p': $r \succ t \succ s$

• Program $q: s \succ r \succ t$

Case 1: r Reports Truthfully

1. Round 1.

- p proposes to r.
- p' also proposes to r.
- q proposes to s.

2. Resident Decisions.

- r receives proposals from p and p'. Since r's true order is $q \succ p \succ p'$ (and q did not propose), r prefers p over p'. Therefore r holds p and rejects p'.
- s holds q.
- t receives no proposal yet.

3. Round 2.

- p' (rejected by r) proposes to its next choice, t.
- t accepts p', having no other offer.

4. Final Matching.

$$r \leftrightarrow p$$
, $s \leftrightarrow q$, $t \leftrightarrow p'$.

Here, r ends up with p. Since q went to s, r cannot do better under truthful reporting.

Case 2: r Misreports by Swapping p and p'

Now suppose r reverses p and p' in his submitted list:

Reported by
$$r: q \succ p' \succ p$$
.

Then:

1. Round 1.

- p proposes to r.
- p' also proposes to r.
- q proposes to s.

2. Resident Decisions.

- r receives proposals from p and p'. According to the reported preference $(p' \succ p)$, r holds p' and rejects p.
- s holds q.

3. Round 2.

- p, rejected by r, proposes next to s.
- Since s truly prefers $p \succ q$, s drops q and holds p.
- q, rejected by s, then proposes to r (its next choice).

4. Round 3.

- r is holding p', but now receives a proposal from q.
- By r's true preference, $q \succ p \succ p'$. So r prefers q and drops p'.

5. Round 4.

- p', dropped by r, proposes next to t.
- t accepts p'.

6. Final Matching.

$$r \leftrightarrow q$$
, $s \leftrightarrow p$, $t \leftrightarrow p'$.

In this scenario, r ends up with q, which is strictly better under r's true preference. Therefore, by lying about the order of two less preferred programs, r can secure a more-preferred match.

Conclusion

This example shows that when programs propose, a resident (receiver) can sometimes benefit from misreporting: truth-telling is not an optimal strategy for the receiving side.

Problem 2 (10 pts)

Arrange in increasing order of asymptotic growth. All logs are in base 2.

- 1. $n^{\frac{5}{3}} \log^2 n$
- 2. $2^{\sqrt{\log n}}$
- 3. $\sqrt{n^n}$
- $4. \ \frac{n^2}{\log n}$
- 5. 2^n

Solution

Define the five functions:

$$f_1(n) = n^{\frac{5}{3}} (\log n)^2$$
, $f_2(n) = 2^{\sqrt{\log n}}$, $f_3(n) = \sqrt{n^n} = n^{\frac{n}{2}}$, $f_4(n) = \frac{n^2}{\log n}$, $f_5(n) = 2^n$.

Comparing $f_2(n)$ with polynomials

$$\log_2(2^{\sqrt{\log_2 n}}) = \sqrt{\log_2 n}, \quad \log_2(n^x) = x \log_2 n.$$

Clearly, for large n, $x \log_2 n$ outgrows $\sqrt{\log_2 n}$. Therefore $2^{\sqrt{\log_2 n}}$ is sub-polynomial. It follows that:

$$f_2(n) < n^x$$
 and Therefore $f_2(n) < f_1(n), f_4(n)$

since f_1, f_4 are polynomial (up to log factors).

Comparing $f_1(n)$ and $f_4(n)$

$$\frac{f_1(n)}{f_4(n)} = \frac{n^{\frac{5}{3}}(\log n)^2}{\frac{n^2}{\log n}} = \frac{n^{\frac{5}{3}}(\log n)^3}{n^2} = \frac{(\log n)^3}{n^{\frac{1}{3}}}.$$

As $n \to \infty$, $n^{\frac{1}{3}}$ eventually outgrows $(\log n)^3$. Therefore

$$f_1(n) < f_4(n).$$

Comparing the exponentials $f_3(n)$ and $f_5(n)$

$$f_3(n) = n^{\frac{n}{2}} = \exp(\frac{n}{2}\ln n), \quad f_5(n) = 2^n = \exp(n\ln 2).$$

For large $n, \frac{n}{2} \ln n$ dominates $n \ln 2$. Therefore

$$n^{\frac{n}{2}} \gg 2^n.$$

Final Ordering

Putting it all together:

$$f_2(n) < f_1(n) < f_4(n) < f_5(n) < f_3(n)$$
.

In explicit form:

$$2^{\sqrt{\log n}} < n^{\frac{5}{3}} (\log n)^2 < \frac{n^2}{\log n} < 2^n < \sqrt{n^n}.$$

Problem 3 (10 pts)

We say that T(n) is O(f(n)) if there exist c and n_0 such that for all $n > n_0$, $T(n) \le cf(n)$. Use this definition for parts a and b.

- 1. Prove that $4n^2 + 3n\log n + 6n + 20\log^2 n + 11$ is $O(n^2)$. (You may use, without proof, the fact that $\log n < n$ for $n \ge 1$.)
- 2. Suppose that f(n) is O(r(n)) and g(n) is O(s(n)). Let h(n) = f(n)g(n) and t(n) = r(n)s(n). Prove that h(n) is O(t(n)).

Solution

(a) Showing $4n^2 + 3n \log n + 6n + 20(\log n)^2 + 11$ is $O(n^2)$

Let

$$T(n) = 4n^2 + 3n \log n + 6n + 20(\log n)^2 + 11.$$

We check each term for a bound proportional to n^2 :

• $4n^2$ is trivially $\leq 4n^2$.

- $3n \log n \le 3n \cdot n = 3n^2$ for $n \ge 1$ (since $\log n \le n$).
- $6n < 6n^2$ for n > 1.
- For large n, $\log n \le n$, Therefore $(\log n)^2 \le n^2$. So $20(\log n)^2 \le 20n^2$.
- $11 \le 11n^2$ for $n \ge 1$.

Summing these bounds shows $T(n) \le (4+3+6+20+11)n^2 = 44n^2$ for $n \ge 1$. Therefore, $T(n) \in O(n^2)$.

(b) Product of two $O(\cdot)$ functions

Assume f(n) is O(r(n)) and g(n) is O(s(n)). Then by definition, there exist constants c_1, c_2 and n_1, n_2 such that for all $n > n_1$, $f(n) \le c_1 r(n)$, and for all $n > n_2$, $g(n) \le c_2 s(n)$. Let $n_0 = \max\{n_1, n_2\}$. Then for $n > n_0$,

$$f(n) g(n) \le c_1 r(n) \cdot c_2 s(n) = (c_1 c_2) (r(n) s(n)).$$

Therefore $f(n) g(n) \in O(r(n) s(n))$.

Problem 4 (10 pts)

The diameter of an undirected graph is the maximum distance between any pair of vertices. If a graph is not connected, its diameter is infinite. Let G be an n node undirected graph, where n is even. Suppose that every vertex has degree at least n/2. Prove that G has diameter at most 2.

Hint: Proof by contradiction

Solution

Let G be an undirected graph on n vertices, with n even, and every vertex of degree at least $\frac{n}{2}$. We will show the diameter of G cannot exceed 2.

Step 1: Contradiction assumption. Assume diam $(G) \ge 3$. Then there exist vertices u, v such that the distance $d(u, v) \ge 3$. In particular:

- 1. u and v are not adjacent (otherwise d(u, v) = 1),
- 2. There is no single vertex adjacent to both u and v (otherwise d(u, v) = 2).

Step 2: Neighborhood sizes. Let N(u) be the neighbors of u and N(v) be the neighbors of v. Since each vertex has degree at least $\frac{n}{2}$,

$$|N(u)| \ge \frac{n}{2}, \quad |N(v)| \ge \frac{n}{2}.$$

Because no vertex is adjacent to both u and v, the sets N(u) and N(v) must be disjoint. Therefore

$$|N(u) \cup N(v)| = |N(u)| + |N(v)| \ge \frac{n}{2} + \frac{n}{2} = n.$$

But there are only n-2 vertices in total other than u and v, so it is impossible for two disjoint neighbor sets to each contain $\frac{n}{2}$ different vertices. We have a contradiction.

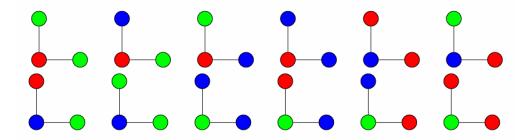

Step 3: Conclude diameter at most 2. Since assuming $\operatorname{diam}(G) \geq 3$ led to a contradiction, it follows that every pair of vertices in G is at distance at most 2. Therefore the diameter is ≤ 2 .

Therefore, any *n*-vertex graph with minimum degree $\frac{n}{2}$ has diameter at most 2.

Problem 5 (10 pts)

Show that there are at least $3 \cdot 2^{n-1}$ ways to properly color vertices of a tree T with n vertices using 3 colors, i.e., to color vertices with three colors such that any two adjacent vertices have distinct colors. Note that it can be shown that there are exactly $3 \cdot 2^{n-1}$ ways to properly color vertices of T with 3 colors but in this problem, to receive full credit, it is enough prove the "at least" part.

For example, there are (at least) $3 \cdot 2^2 = 12$ ways to color a tree with 3 vertices as show below:

Problem 6 (Extra Credit: 10 pts)

Given a directed graph G with n vertices $V = \{1, 2, \dots, n\}$ and m edges. We say that a vertex j is reachable from i if there is a directed path from i to j. Design an O(m+n)-time algorithm (show the pseudo-code) that for any vertex i outputs the smallest label reachable from i. For example, given the following graph you should output 1,2,2,2,1 corresponding to the smallest indices reachable from vertices 1,2,3,4,5 respectively.
